Chapter 1

Introduction

. . .

We're extending the work done by Jacob Højgaard in his Masters Thesis 'Securing Single Sign-On Systems With Executable Models'. Jacobs research has focused on the current implementation of NemID and therefore describes, outlines and models the current system used in Denmark as of May 2013.

Jacobs report sums up some of the problems with the current implementation of NemID, these problems include but are not limited to the system being very opaque. We're in the age of information, we want to be able to get information about everything regardless if it's in our best interest or not. NemID is not sharing any information about the internals of the system. If a person wanted to test some part of the NemID system, they would first have to analyze the public parts of the system to figure out how to communicate with the NemID system, afterwards all they would be able to do, would be black box testing. We need a system that is transparent, testable by everyone and doesn't cost a whole lot. For the sake of being able to reference this system through out the report, we will refer to it as OpenNemID.

1.1 Objectives

Some explaining text here

- 1. Describe and outline the OpenNemID protocol, including but not limited to registration and login.
- 2. Formalize the specification of OpenNemID in F^* to the extent possible.

1.2. SCOPE Chapter 1

1.2 Scope

This project has had it focus towards specifying a new protocol that could replace NemID. The intent of this project is therefore not to develop a complete system, but to make the specification for a system that could then later be developed based on the specification.

1.3 Background

. . .

Chapter 2

Technical background

- 2.1 SAML protocol
- 2.1.1 OIOSAML
- 2.2 Static analysis
- 2.3 Selection of verification tool

 \mathcal{F}^* - formal specification language that is also executable

2.4 N-factor authentication

Viderudvikling af two factor authentication

Chapter 3

Modelling the protocol

Before formalizing the protocol, it's required to specify and explain some of the words, concepts and meanings used within the protocol. This will be done by using graphical representation of the message flow.

3.1 Protocol prerequisites

It's important to have some requirements as to how the systems should function. The requirements helps define certain properties the involved participants must have or obey to. It's important to have some requirements as to how the systems should function. The requirements helps define certain properties the involved participants must have or obey to.

3.1.1 Shared

The NemLog-in specification mandates the use of OIOSAML, this will most likely not be excluded, therefore we assume that OpenNemID also has to use it. Further OIOSAML mandates the use of one-way SSL/TLS for all bindings, the mandate does not specify a specific version, though it can be assumed that a minimum version of SSL 3.0 due to the fact that SSL 2.0 is in general considered deprecated. We assume the use of SSL 3.0 or TLS 1.0 in this report.

As mentioned before, SAML uses the browser to transfer messages from one principal to the other. The way to do this is through HTTP REDIRECTs, which could be either a HTTP-GET REDIRECT or a HTTP-POST REDIRECT. The HTTP protocol accepts a Location head in the HTTP RESPONSE which indicates where the browser should redirect to. The location header redirect will act as a HTTP-GET REQUEST which excludes the usage of POST data, thereby limiting the amount of data that can be transferred. To overcome this problem HTTP-POST REDIRECTs are used, these are not a part of the HTTP protocol, but is synthesized by using JavaScript to emulate a regular

HTTP-POST REQUEST. Therefore it is required for the users browser to follow redirects and to have JavaScript enabled.

For there to be any actual messages to flow between the service provider and identity provider, it's assumed that they reside in different domains and are different entities.

The identity provider is only to issue assertions to known service providers, this requires that SAML metadata has been changed beforehand. The certificates used for signing and encrypting has to be checked for revocation and validity whenever used.

To summarize:

- 1. OIOSAML mandates the use of SSL(3.0)/TLS(1.0).
- 2. The browser must follow redirects.
- 3. The browser must have JavaScript enabled.
- Service provider and identity provider are different entities residing in different domains.
- 5. SAML metadata must have been exchanged between the service provider and identity provider.
- Signature check and encryption requires validity/revocation check of the certificate.

3.1.2 NemID specifics

It's required for the OCES certificates used for signing and encrypting to have been issued by DanID.

3.1.3 OpenNemID specifics

For the communication between the authentication provider and the identity provider, a secure tunnel must have been set up. Further the user must have registered at the authentication provider.

We have assume the availability of a web cryptography API in this report. A web cryptography API has not yet been standardized, but a standardization is being worked on, a draft is available [3].

3.2 Formalizing protocol messages

The UML communication diagrams depicting the protocols are made up of two or more participants, henceforth principals, and the messages flowing through the system. The line between two principals indicates a channel where communication can flow, this channel is assumed to be a secure channel, meaning for HTTP messages, the HTTPS protocol would be used. An arrow indicates the

direction of the message and the text on top of the arrow is the message being sent. The messages does not conform to any specific formalism, but follows a simple syntax. Messages are, very applicable, named in accordance with their HTTP protocol verb. The messages are to be interpreted the following way:

GET means a HTTP-GET request, the parameter is the resource being requested.

POST means a HTTP-POST request, the parameters are the destination for the request followed by the data being submitted.

REDIRECT means either a HTTP-REDIRECT or a JavaScript redirect, whichever is used is not important for the purpose of the description. The parameters are the destination for the redirect followed by the parameters to include in the redirect.

RESPONSE means a HTTP-RESPONSE messages. The parameters are either the data included in the response or a HTTP status code indicating the type of the response along with a message, this is used for indicating when error happen.

DELEGATE means forwarding the data from the previous request, the parameters are the parameters from the previous request that were to be delegated.

AUTHENTICATE is to be interpreted as the sequence of actions required to be authenticated at the specified NFactorChallenge. The AUTHENTICATE message is defined this generically on purpose, as the way a user would authenticate for a NFactorChallenge can vary a lot depending on which technology is used (SMS, Facebook, phone call etc.).

3.3 Communication model

To make the changes from NemID to OpenNemID clear, we will first show the communication diagram for NemID, afterwards we will show the communication diagram for OpenNemID. Both diagrams make use of abbreviations, these abbreviations are listed at the top of the diagram along the word or phrase they abbreviate. We have tried to comply with Jacobs data as much as possible, due to the fact that his report conforms to the requirements mandated by Digitaliseringsstyrrelsen.

3.3.1 Message processing

Information regarding the processing of messages have not been included in the diagrams, this is to prevent cluttering of the diagrams. To circumvent this, the processing rules will be described afterwards. The descriptions will be linked to a specific process number, meaning Process 3 would be the handling and

response of message 3 in the diagram. Messages that are self-explanatory will not be further described.

3.3.2 Communication diagram for NemID

Description of the message processing for this diagram has been left out of our report, they can however be found in Jacob Højgaards report [1].

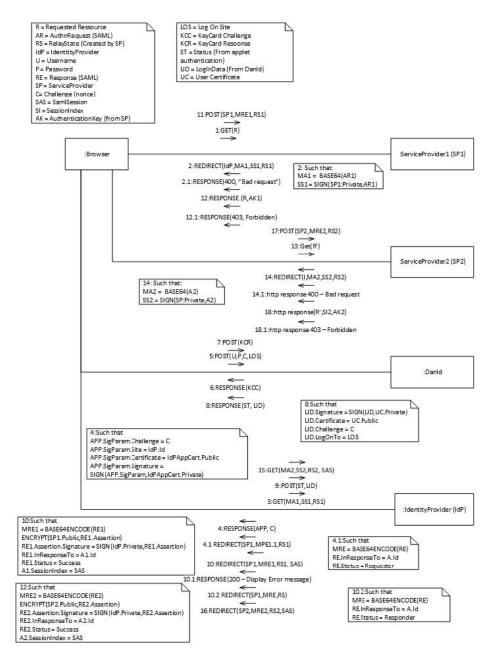

Figure 3.1: Communication diagram for the complete NemID protocol [1]

3.3.3 Communication diagram for OpenNemID

In this diagram, we have chosen to leave out the additional request to another service provider than the one initially used, this is due to the communication flow being exactly the same as in Jacobs diagram, see Figure 3.1, message 13 to 18

In the communication diagram for OpenNemID, DanID have been replaced by AuthenticationProvider, for the sake of our protocol it is of no greater importance which company handles the authentication.

We have strived to minimize the amount of messages flowing through the system to limit the amount of possible attack points for a potential adversary. We have also eliminated the need for transporting sensitive data, such as the users login data, from the authentication provider to the identity provider, by mandating that the identity provider and the authentication provider exchange information using a secure tunnel without the user being able to interfere.

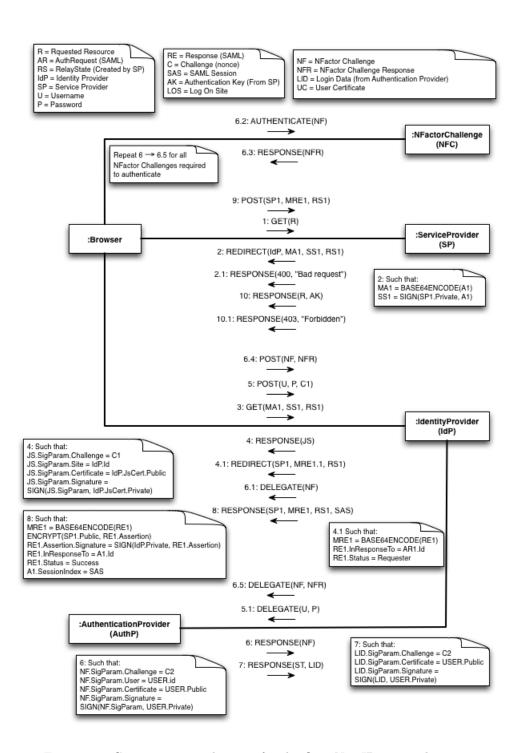

Figure 3.2: Communication diagram for the OpenNemID protocol

Message descriptions

Process 1 describes the creation of the AuthRequest at the service provider when a resource has been requested. Is the request resource not found a 400 Bad-Request message is returned. The use of url encoding (UrlEnc) and base64 encoding (Base64Enc) is to ensure that the data can be transferred as parameters in the URL.

SAML and OIOSAML has a substantial amount of processing rules that dictates the processing of messages, disobeying these will cause an error. For the sake of communication the descriptions have been kept to a minimum, not listening all scenarios that would cause an error.

Algorithm 1 Process 1

```
Require: GET is well-formed and IdP.Public and SP.Private

if R exists then

AR ← CreateAuthRequest()

SAR ← SIGN(AR, SP.Private)

MA ← UrlEnc(Base64Enc(DeflateCompress(AR)))

RS ← UrlEnc(Base64Enc(R))

return REDIRECT(IdP, MA, SAR, RS)

else

return RESPONSE(400, BadRequest)

end if
```

Process 3 describes the handling of a *AuthRequest* at the identity provider. The request will be handled in one of two ways depending on whether the AuthRequest could be verified. In the case of verification failing, a SAML response will be returned indicating an error. Otherwise a page for requesting the users credentials is returned. The page returned will also contains the signed JavaScript for handling the OpenNemID specific actions. The JavaScript is signed using a certificate, *IdPJsCert*, this certificate has to have been issued by the authentication provider.

A challenge (nonce) is generated, this is to prevent an attack where an adversary would submit an identical request to one that has already been submitted, also known as a *replay attack*. If the challenge wasn't introduced the second identical request would also be accepted.

A cookie is created containing the AuthRequest, signed AuthRequest along with the relay state. This is done to free the identity provider from having to store the data, thereby granting more statelessness.

Algorithm 2 Process 3

```
Require: GET is well-formed and IdP.Private and SP.Public and Id-
  PJsCert.Public and IdP has JavaScript from AuthP
  AR \leftarrow DeflateDecompress(Base64Dec(UrlDec(MA)))
  if VERIFY(AR, SAR, SP.Public) then
    C1 \leftarrow GenChallenge()
    JS \leftarrow GetStoredJavaScript()
    JS.SigParams.Challenge \leftarrow C1
    JS.SigParams.Certificate \leftarrow IdPJsCert.Public
    JS.SigParams.Signature \leftarrow SIGN(JS.SigParams, IdPJsCert.Private)
    ARC \leftarrow CreateCookie(MA, SAR, RS)
    return RESPONSE(JS, ARC)
  else
    RE \leftarrow CreateResponse()
    RE.InResponseTo \leftarrow AR
    RE.Status \leftarrow VerificationFailied
    MRE \leftarrow Base64Enc(RE)
    return REDIRECT(SP, MRE, RS)
  end if
```

As specified in the formalization, it's required for the browser to allow JavaScript. The username, U and password, P for the user is not stored and fetched directly, but will be input by the user manually, though for the description of process 4 it will be assumed that they are both ready right away. Before the user is prompted for username and password, the JavaScript is verified. The challenge is submitted together with the username and password. Hashing of the username and password has been omitted as it holds no functional enhancement towards the protocol.

Algorithm 3 Process 4

```
\label{eq:Require: U and P and Browser allows JavaScript} \\ SigParams \leftarrow Js.SigParams \\ \textbf{if VERIFY}(SigParams, SigParams.Signature, SigParams.Certificate) \textbf{then} \\ C1 \leftarrow SigParams.Challenge \\ \textbf{return POST}(U, P, C1) \\ \textbf{else} \\ \textbf{print ERROR} \\ \textbf{end if} \\ \end{aligned}
```

In process 5 the identity provider confirms that the challenge received matches a previously issued challenge, and that is has not already been used. A SAML response indicating an error is returned if the challenge is not accepted, otherwise the username and password will be delegated to the authentication provider.

Algorithm 4 Process 5 Require: POST is well formed if C1 matches challenge issued by IdP and C1 is valid then Delegate U and P to AuthP else return RESPONSE(ERROR) end if

Process 5.1 describes how the username and password submitted is used to identify a user at the authentication provider. If a user is found and is valid, a challenge will be generated and the next N-Factor challenge for the user will be fetched. The N-Factor challenge is signed and then returned. Were no valid user found based on the supplied username and password, a SAML response message indicating an error will be returned.

```
Algorithm 5 Process 5.1

USER ← GetUser(U, P)

if USER is valid then

C2 ← GenChallenge()

NF ← GetNextNFactorChallenge(USER)

NF.SigParam.User ← USER

NF.SigParam.Challenge ← C2

NF.SigParam.Certificate ← USER.Public

NF.SigParam.Signature ← SIGN(NF.SigParam, USER.Private)

return RESPONSE(NF)

else

return RESPONSE(ERROR)

end if
```

Process 6 show how the identity provider has to delegate messages from the browser to the authentication provider and vice versa. In this case the N-Factor challenge is to be delegated. If the authentication provider returned an error or the identity provider cannot verify the N-Factor challenge received, a SAML response message indicating an error will be returned to the browser. If the N-Factor challenge is verified, it is then delegated to the browser.

```
SigParams ← NF.SigParams

if VERIFY(SigParams, SigParams.Signature, SigParams.Certificate) then

Delegate NF to Browser

else
```

Delegate ERROR to Browser end if

Algorithm 6 Process 6

The browser also verifies that the N-Factor challenge is valid in process

6.1. An attempt to authenticate the N-Factor challenge is then performed. Due to the challenges genericity, the authentication process will not be further described.

```
Algorithm 7 Process 6.1

SigParams ← NF.SigParams

if VERIFY(SigParams, SigParams.Signature, SigParams.Certificate) then

AUTHENTICATE(NF)

else

print ERROR

end if
```

In process 6.2, the genericity of the N-Factor challenges once more results in a minimal description. The way the authentication attempts will be handled depends on the N-Factor challenge, therefore to simplify the description, it is assumed that a result conforming to a specific template is returned.

Algorithm 8 Process 6.2 NFR ← NFactorResult(NF) return RESPONSE(NFR)

Process 6.5 describes the handling of a N-Factor challenge result. First off, the N-Factor challenge is verified to make sure that it has not been altered. Then it is checked whether or not the N-Factor challenge result is acceptable for the N-Factor challenge. In the case of acceptance the user is fetched. If the user has not yet completed all N-Factor challenges required to authenticate at the authentication provider, then the next challenge is fetched, signed and returned to the user. Process 6 to 6.5 is then repeated until no more N-Factor challenges are required, in which case login data for the user is created and returned to the identity provider. In case of the N-Factor challenge not passing verification or the N-Factor challenge result is not accepted a SAML message indicating an error is returned.

Algorithm 9 Process 6.5

```
Require: User
                                                        (NF.SigParams.USER,
                        identifiable
                                            by
  NF.SigParams.Certificate)
  SigParams \leftarrow NF.SigParams
  if VERIFY(SigParams, SigParams.Signature, SigParams.Certificate) then
    if NFR is acceptable result of NF then
       USER \leftarrow GetUser(SigParams.USER, SigParams.Certificate)
      C2 \leftarrow GenChallenge()
      if USER.HasNextChallenge then
         NF \leftarrow GetNextNFactorChallenge(USER)
         NF.SigParams.User \leftarrow USER
         NF.SigParams.Challenge \leftarrow C2
         NF.SigParams.Certificate \leftarrow USER.Public
         NF.SigParams.Signature \leftarrow SIGN(NF.SigParams, USER.Private)
         return RESPONSE(NF)
      else
         LID \leftarrow CreateLogInData(USER)
         ST \leftarrow "OK"
         return RESPONSE(ST, LID)
      end if
    else
      return RESPONSE(ERROR)
    end if
  else
    return RESPONSE(ERROR)
  end if
```

In process 7 it is described how the identity provider handles when a user has been authenticated at the authentication provider. If the returned status does not equal an acceptance criteria, the status is returned to the browser to indicate an error, the status would further describe the error. When the status is accepted the cookie created in process 3 is fetched and the contents on the cookie are extracted.

The initial AuthRequest extracted from the cookie is verified. Failed verification results in the user being redirected to the service provider with information indicating that the AuthRequest could not be granted.

When verification succeeds, an assertion is build based on the login data received from the authentication provider.

Algorithm 10 Process 7

```
Require: SP.Public and LID is well-formed and ARC cookie present
  if ST = "OK" then
     MA \leftarrow ARC.AR
     SAR \leftarrow ARC.SAR
     RS \leftarrow ARC.RS
     AR \leftarrow DeflateDecompress(Base64Dec(UrlDec(MA)))
     if VERIFY(AR, SAR, SP.Public) then
       A \leftarrow BuildAssertion(LID.Certificate)
       SI \leftarrow GenerateSessionIndex()
       A.InResponseTo \leftarrow AR
       A.Issuer \leftarrow IdP
       A.Audience \leftarrow SP
       A.SessionIndex \leftarrow SI
       A.Signature \leftarrow SIGN(A, IdP.Private)
       EA \leftarrow ENCRYPT(A, SP.Public)
       RE \leftarrow CreateResponse()
       RE.Assertion \leftarrow EA
       RE.InResponseTo \leftarrow AR
       RE.Status \leftarrow "Success"
       MRE \leftarrow DeflateCompress(Base64Enc(UrlEnc(RE)))
       SAS \leftarrow CreateSAMLSession(SI, SP, LID.CertificateSubject)
       return REDIRECT(SP, MRE, RS, SAS)
     else
       RE \leftarrow CreateResponse()
       RE.InResponseTo \leftarrow AR

end if
```

Chapter 4

Modelling with F*

This chapter will introduce the language F^* that can be used to model a security protocol. Despite being a formal specification language F^* is also executable. F^* is described as a *A Verifying Compiler for Distributed Programming*. This chapter will describe how we have used F^* to build a formal specification of OpenNemID.

4.1 Introducing F*

 F^* is a research language from Microsoft Research. F^* primarily subsumes two research languages from Microsoft Research, $F7^1$ and $Fine^2$. F^* is at this time considered to be an α -release. The purpose of designing F^* is to enable the construction and communication of proofs of program properties and of properties of a program's environment in a verifiable secure way. F^* is a dialect of ML and compiles to .NET bytecode in type-preserving style. This means that it can interop with other .NET languages and the types defined in F^* can be used by other .NET languages without loosing type information. Furthermore there also exists a fully abstract compiler from F^* to JavaScript. This makes it possible to deploy F^* programs on web pages as JavaScript meanwhile there is a formal guarantee that the program still behaves just as they would according to F^* semantics. The compiling and type-checking of F^* code utilizes the $Z3^3$ SMT solver for proving assumptions made with refinement types. F^* has been formalized and verified using Coq^4 .

¹http://research.microsoft.com/en-us/projects/f7/

²http://research.microsoft.com/en-us/projects/fine/

³http://z3.codeplex.com/

⁴Coq is an interactive theorem prover written in OCaml

4.2 Syntax and semantics

 F^* inherits syntax and semantics from ML. F^* is a functional language which means that it has features like immutability by default, polymorphic types and type inference. In Listing 4.1 we have shown the classic Hello World example in F^* . This is the simplest way this example could have been written. This example shows how to specify a main method by defining a function _ (underscore) at the end of a module. This will instruct the compiler to make an .exe file instead of a dll.

```
module HelloWorld
let _ = print "Hello world!"
```

Listing 4.1: Hello World example in F*

The example in listing 4.2 shows how to explicitly specify types with the colon operator and the val declaration for defining function signatures. This example defines the function multiply that takes two ints as parameters and returns an int. After that it defines the corresponding let binding which defines multiplies the 2 arguments. It is important to note that not defining the corresponding let binding will not cause the compilation to fail but give the following warning: Warning: Admitting value declaration Multiplication.multiply as an axiom without a corresponding definition. So the value declaration was valid but there is no concrete implementation supporting this claim.

```
module Multiplication

val multiply: x:int -> y: int -> int

let multiply x y = x * y

let mul = multiply 3 4
```

Listing 4.2: Multiplication example in F*

4.3 Refinement types

 F^* has derived the feature refinement types from the Microsoft Research projects, F7 and Fine. Refinement types are used to make type safe refinements of existing types. Thus it is possible to restrict or refine values more than their original type. Listing 4.3 shows an example with the refinement nat of int that states that nat will always be zero of larger, i.e. a natural number. The example also shows an attempt to assign -1 to a type of nat which will fail type checking.

```
1 (*Declare a type nat of natural numbers*)
2 type nat = i:int{0 <= i}
3
4 let x:nat = 1
5 let y:nat = 0</pre>
```

```
let z:nat = 1 - 2 (*Will fail typecheck*)
```

Listing 4.3: Simple refinement types in F*

Refinement types have the form $x:t\{t'\}$ as shown above. So a refinement type is created by taking an existing type and decorate it with an expression in curly brackets. In the example above the refinement type is a simple boolean expression but refinements are not limited to boolean expression. This is extended in F^* by its kind-system. Kinds can be seen as an abstraction over types - types can either have or be of a kind. The *-kind indicates 'regular types' in F^* . This covers all the possible types to create in a regular type system for a programming language like Java. Refinement types are of the E-kind and not of the *-kind. The E(rasable)-kinds have no significance at runtime. They only have an effect at the compiling time during type checking.

4.4 Formalizing OpenNemID by using Jacob's work

Since we are extending Jacob's work with the authentication part of the protocol we used his code as a reference for implementing the rest of the OpenNemID protocol. In listing 4.4 we show Jacob's implementation of the Identity Provider. He has implemented a recursive function *identityprovider* declared with the *val* binding just above it. The function declared takes 2 arguments and returns *unit*.

The arguments

- 1. a principal for identifying the identity provider
- 2. a principal for identifying the client.

Unit means the same as void in Java.

```
module Identityprovider
   open SamlProtocol
   open Crypto
       handleUserAuthenticated me user client authnrequest =
        <mark>tch</mark> authnrequest <mark>wi</mark>
       MkAuthnRequest(reqid, issueinst, dest, sp, msg, sigSP) ->
          let pubksp = CertStore.GetPublicKey sp in
         if (VerifySignature sp pubksp msg sigSP) then
            (assert (Log sp msg);
            let assertion = IssueAssertion me user sp reqid in
13
                           CertStore.GetPrivateKey me
14
                myprivk =
15
            assume(Log me assertion);
              t sigAs = Sign me myprivk assertion in
16
                signAssertion = AddSignatureToAssertion assertion
                sigAs i
                encryptedAssertion = EncryptAssertion sp pubksp
```

```
signAssertion
                       AuthResponseMessage me sp encryptedAssertion
20
            let resp
           SendSaml client resp) (*10*)
21
22
            SendSaml client (Failed Requester) (*10.2*)
23
24
   val identityprovider: me:prin -> client:prin -> unit
25
27
   let rec identityprovider me client =
    let req = ReceiveSaml client in (*3 & 11*)
28
29
    match req w:
      AuthnRequestMessage (issuer, destination, message, sigSP) ->
30
       let pubkissuer = CertStore.GetPublicKey issuer
          (VerifySignature issuer pubkissuer message sigSP) then
32
         (assert (Log issuer message);
33
         let challenge = GenerateNonce me in
34
          let resp = UserCredRequest challenge in
35
         SendSaml client resp; (*4*)
37
         identityprovider me client (*Start over*))
38

Listing 4.4: Jacob's Identity Provider Implementation

The recursive function identityprovider starts by receiving a SAML message from the client. It then matches the request with a SamlMessage. AuthnRequestMessage or SamlMessage. UserAuthenticated type. When matched with an AuthnRequest message it verifies the Service Provider's signature of the message by the function VerifySignature which is shown in listing 4.5. The function takes a principal, the principals public key, a message and a signature. It returns a boolean indicating if the check passed. The return type however has a refinement type that relates the message to the principal if the verification passes. ==> should be as implication therefore stating that the predicate is valid. If the verification of the Service Provider's signature of the AuthnRequestMessage passes it creates a nonce to be related to this user when the user has authenticated himself/herself by NemID and sends the response to the user. When the user has authenticated through NemID the function handleUserAuthenticated is called. The function's

purpose is to issue a signed assertion and sending the AuthResponseMessage to the user. The signature for signing messages takes 4 arguments - the principal, the signer, the private key of the principal and the message to be signed. The message is annotated with a refinement type $\{Log\ p\ msg\}$. This refinement type is an E-kinded type that takes a principal and a string as constructor elements. The val declaration for a method Sign in listing 4.5 requires the predicate $\{Log\ p\ msg\}$ to be true before it can typecheck. This means that the message to sign is related to the principal signing the message. Securing this is done by calling $assume\{Log\ me\ assertion\}$ before signing the message. The predicate is by virtue of this "verified". After this the assertion is encrypted by using the Service Provider's public key and sent within an AuthResponseMessage to the user.

```
type pubkey :: prin => *

type privkey :: prin => *

type Log :: prin => string => E

val Sign: p:prin
    -> privkey p
    -> msg:string{Log p msg}
    -> dsig

val VerifySignature: p:prin
    -> pubkey p
    -> msg:string
    -> dsig
    -> b:bool{b=true ==> Log p msg}
```

Listing 4.5: Cryptographic elements

In listing 4.5 we show the declaration of the types for private key (privkey) and public key (pubkey). These types are declared by using the F* syntax for constructing dependent types (the double colon). This means that a type pubkey will have a constructor that takes a prin (principal) and returns a type of *-kind. This is still abstract and the type has no actual constructor.

4.5 OpenNemID specified in F*

The code in this section represents the state of the project now. This is in no way a complete implementation of the protocol. Implementation was carried out in an incremental manner. First the focus was on understanding Jacob's work and expanding that with the authentication part (Authentication Provider) of the protocol, which before was done by NemID, and then adding the functionality of creating login, establishing connection between Identity Provider and the Authentication Provider and so on. All source code that has been produced in this project can be found on the source code sharing community Github⁵. The F* code for the protocol is organized in 10 modules:

^{51... // ::1 1 /1 : : . . . /}O N ID

- 1. The TypeFunc module
- 2. The SamlProtocol module
- 3. The Crypto module
- 4. The CertStore module
- 5. The Messaging module
- 6. The Service Provider module
- 7. The Identity Provider module
- 8. The Database module
- 9. The Authentication Provider module
- 10. The Browser module

The modelling follows the principles for cryptographic protocol modelling outlined by Dolev & Yao⁶. In the following we will explain the important principles for each module and the relation to the algorithms outlined in chapter 3.

4.5.1 Specification of the type functionality module

```
module TypeFunc

type Authentication =
    | Facebook: id:int -> Authentication
    | SMS: generated:int -> Authentication
    | Google: id:int -> Authentication
    | OpenId: id:int -> Authentication
```

Listing 4.6: TypeFunc module

The *TypeFunc* module provides the type authentication which is used for the different kinds of n factor authentication. Note that currently there is only an id associate with each type of authentication for simplicity. This needs to be modified so that each type is more explicit and holds the correct information for authentication.

4.5.2 Specification of the SAML Protocol

```
module SamlProtocol

open Crypto
open TypeFunc

s
```

 $^{^6}$ Cryptographic primitives are assumed perfect and cyphers cannot be decrypted without the the proper decryption key

```

       signedtoken -> Assertion
       DecryptAssertion: receiver:prin -> privkey receiver ->
       Assertion -> (signedtoken * dsig)
```

Listing 4.7: Specification of the SAML Protocol elements

The SamlProtocol module is taken directly from Jacob's code and only modified to support more and different SamlMessage that are needed in our specification of OpenNemID. This module's purpose is the specification of messages and to provice functions for sending and receiving messages. Note that the functions for sending and receiving messages have no runtime implementation. They are only specified by the val declaration. The SAML Protocol is used for the communication between the principals in the OpenNemID protocol in a login session. The intention with these functions is that they will handle the mapping of protocol elements to the network.

4.5.3 Specification of cryptographic elements

```
module Crypto

open Protocol
open TypeFunc

type prin = string
type pubkey :: prin => *
type privkey :: prin => *
type dsig
type nonce = string
type cypher

49
50
       cypher
       string
51
   val GenerateNonce: prin -> nonce (*Add refinement to ensure
```

Listing 4.8: Specification of cryptographic elements

The *crypto* module is taken directly from Jacob's code and only modified to support signing and verification of the authentication type. The purpose of the *crypto* is providing the cryptographic functions to sign and verify both messages and the authentication type also the encryption and decryption of messages. The *crypto* module utilizes the refinement type to ensure that signed messages and authentications have typed dependency to the signing principal. It does not have a concrete implementation as of now.

4.5.4 Specification of certificate store module

```
module CertStore
```

```
open Crypto

val GetPublicKey: p:prin -> pubkey p
val GetJSPublicKey: p:prin -> pubkey p
(*Prin needs to be updated to include credentials*)
val GetPrivateKey: p:prin -> privkey p
val GetJSPrivateKey: p:prin -> privkey p
```

Listing 4.9: Abstract certificate store

The CertStore module is taken from Jacob's code and expanded with functionality to support JavaScript public and private keys. This module provides four abstract functions for retrieving certificates from a certificate store. The functions use the value dependent syntax for relating a principal to the certificate keys. As Jacob has written in a comment the principal could be updated to include credentials because this is a quite naive implementation. It is quite naive because all you need to obtain the private key of a principal is the name of the principal.

4.5.5 Specification of the messaging protocol

```
module Messaging
   open Crypto
   open TypeFunc
   type Status =
      Successful: Status
     Unsuccessful: Status
   type Message =
      NewSiteRequest: idp:prin -> Message
11
      ChallengeResponse: challenge:nonce -> Message
12
      IdpChalResponse: challenge:nonce -> Message
13
      AcceptedIdp: idp:prin -> pubkey:pubkey idp -> authp:prin ->
14
        authpubkey:pubkey authp -> signedjavascript:string ->
       Message
    | RequestForLogin: userid:string -> password:string -> email:
        string -> Message
      ReqLoginResponse: challenge:nonce -> Message
16
17
      CreateLogin: generatedpassword:string -> challenge:nonce ->
        Message
      ChangeUserId: userid:string -> newUserId:string -> password:
       string -> Message
      ChangePassword: userid:string -> password:string ->
19
       newPassword:string -> Message
      UserRevokeIdp: userid:string -> password:string -> idp;
20
        string -> Message
      AddNfactor: userid:string -> password:string -> nfact:
21
        Authentication -> Message
      RemoveNfactor: userid:string -> password:string -> nfact:
        Authentication -> Message
      StatusMessage: Status -> Message
```

```
val SendMessage: prin -> Message -> unit
val ReceiveMessage: prin -> Message
```

Listing 4.10: Specification of the Messaging protocol

The *Messaging* module is responsible for 2 things - the specification of messages and providing functions for sending and receiving these messages. As the *SamlProtocol* module the functions for sending and receiving are specified only by the *val* declaration and has no concrecte runtime implementation. This module is used to model the communication between Identity Provider / user and the Authentication Provider when wanting to establish a secure connection and creating and/or changing an user's login.

4.5.6 Specification of the Service Provider

```
module Serviceprovider
   open SamlProtocol
   open Crypto
   val serviceprovider: me:prin -> client:prin -> idp:prin ->
   let rec serviceprovider me client idp =
    let req = ReceiveSaml client in
    match req w:
       SPLogin (url) ->
11
       let authnReq = CreateAuthnRequestMessage me idp in
assume(Log me authnReq);
12
13
        let myprivk = CertStore.GetPrivateKey me
14
       let sigSP = Sign me myprivk authnReq in
let resp = AuthnRequestMessage me idp authnReq sigSP in
15
16
       SendSaml client resp;
17
       serviceprovider me client idp
18
       AuthResponseMessage (issuer, destination, encassertion) ->
        let myprivk = CertStore.GetPrivateKey me in
20
21
            assertion = DecryptAssertion me myprivk encassertion in
        match assertion wit
22
         SignedAssertion (token, sigIDP) ->
23
          let pubkissuer = CertStore.GetPublicKey idp in
25
             VerifySignature idp pubkissuer token sigIDP
26
27
            (assert(Log idp token);
            let resp = LoginResponse "You are now logged in" in
28
            SendSaml client resp)
29
          else SendSaml client (DisplayError 403);
30
31
          serviceprovider me client idp
32
         -> SendSaml client (DisplayError 400);
            serviceprovider me client idp
```

Listing 4.11: Specification of service provider

The service provider is taken and directly from Jacob's code and it is not modified in any way. The service provider implements algorithm 1 and 11 in section 3.3. The module is constructed to accept SAML messages of type SPLogin and AuthResponseMessage. If the service provider receives another type of message it will return a HTTP error. Contrary to algorithms 1 and 11 the service provider does not implement encoding and decoding because this is expected to be handled by the SamlProtocol module.

4.5.7 Specification of the Identity Provider

The specification of the Identity Provider is divided into several listings for the sake of understandability.

```
module Identityprovider
   open SamlProtocol
   open Crypto
   open TypeFunc
   open Messaging
   val userloggedin: user:prin -> bool
   val getjavascript: string
       userlogin: user:prin -> unit
   val decodeMessage: message:string -> AuthnRequest
   val getauthnrequest: user:prin -> challenge:nonce ->
        AuthnRequest
   val getuserchallenge: user:prin -> nonce
       relatechallenge: user:prin -> challenge:nonce -> unit
14
   val verifychallenge: user:prin -> challenge:nonce -> bool
   val relate: user:prin -> challenge:nonce -> authnReq:
16
        AuthnRequest -> unit
17
   val identityprovider: me:prin -> user:prin -> authp:prin ->
18
19
   let rec identityprovider me user authp =
    let request = ReceiveSaml user in
21
22
        ch request
      AuthnRequestMessage(issuer, destination, message, sigSP) ->
23
       et pubkissuer = CertStore.GetPublicKey issuer
24
     if (VerifySignature issuer pubkissuer message sigSP) then
     (assert (Log issuer message);
let authnReq = decodeMessage message in
let myprivk = CertStore.GetPrivateKey me in
26
27
28
      if not (userloggedin user) the
29
       let challenge = GenerateNonce me in
      relate user challenge authnReq;
31
32
       relatechallenge user challenge;
        et js = getjavascript in
33
       assume(Log me js);
       let myprivk = CertStore.GetJSPrivateKey me in
let sigIdP = Sign me myprivk js in
36
       let resp = UserCredRequest js challenge sigIdP in
       SendSaml user resp;
       identityprovider me user authp
```

```
let assertion = IssueAssertion me user issuer authnReq in
41
       assume(Log me assertion);
42
      let myprivk = CertStore.GetPrivateKey me in
let pubksp = CertStore.GetPublicKey issuer in
43
44
       let sigAs = Sign me myprivk assertion in
45
46
       let signAssertion = AddSignatureToAssertion assertion sigAs
       let encryptedAssertion = EncryptAssertion issuer pubksp
           signAssertion ir
       let resp = AuthResponseMessage me issuer encryptedAssertion
48
       SendSaml user resp)
49
50
     SendSaml user (Failed Requester);
51
      identityprovider me user authp
52
53
      Login (loginInfo, challenge) ->
     if (verifychallenge user challenge) then
54
       let req = LoginRequestMessage me authp loginInfo in
      SendSaml authp req;
56
57
       handleauthresponse me user authp;
       identityprovider me user authp
58
59
60
      SendSaml user (DisplayError 400);
       identityprovider me user authp
61
62
      UserAuthResponse(authInfo, challenge, sigAuth) ->
      let req = NfactAuthRequest me authp authInfo challenge
63
         sigAuth
     SendSaml authp req;
65
     handleauthresponse me user authp;
      identityprovider me user authp
66
      _ -> SendSaml user (DisplayError 400);
     identityprovider me user authp
```

Listing 4.12: Handling and delegation of a user's requests

This part of the identity provider implements the algorithms (INDST NR p algorithmente). The identity provider accepts the three SAML messages Authn-RequestMessage, Login and UserAuthResponse from the user.

- 1. The AuthnRequestMessage branch decodes the message and if the user has not logged in previously it sends a UserCredRequest back with the JavaScript and a nonce to be used for relating the login at the Identity Provider prompting the user to give his or her login information. If the user has already logged in previously it issues an assertion to the user.
- 2. The *Login* branch handles the user's login information which is the response the user provides after receiving the *UserCredRequest*. This branch verifies that the nonce from the user is the correct one and if it is correct it delegates the login information to the Authentication Provider and then calls the function handleauthresponse which we will explain later in this section. If the nonce is incorrect it returns a HTTP error.
- 3. The *UserAuthResponse* branch handles the user's n factor authentication information and delegates the information to the Authentication Provider.

```
val handleUserAuthenticated: me:prin -> user:prin -> authnReq:
       AuthnRequest -> unit
   let handleUserAuthenticated me user authnReq =
    match authnReq wi
    | MkAuthnRequest(issueinst,dest,sp,msg,sigSP) ->
     let pubksp = CertStore.GetPublicKey sp in
   if (VerifySignature sp pubksp msg sigSP) then
     (assert (Log sp msg);
     let assertion = IssueAssertion me user sp authnReq in
     let myprivk = CertStore.GetPrivateKey me in
     assume(Log me assertion);
12
     userlogin user;
      let sigAs = Sign me myprivk assertion in
13
     let signAssertion = AddSignatureToAssertion assertion sigAs
     let encryptedAssertion = EncryptAssertion sp pubksp
15
         signAssertion in
     let resp = AuthResponseMessage me sp encryptedAssertion in
16
     SendSaml user resp)
17
18
    SendSaml user (Failed Requester)
19
   val handleauthresponse: me:prin -> user:prin -> authp:prin ->
20
       unit
   let handleauthresponse me user authp =
22
23
    let resp = ReceiveSaml authp in
    match resp with
24
    LoginResponseMessage(issuer, destination, authmethod,
        challenge, sigUser) ->
     let pubkeyuser = CertStore.GetPublicKey user in
26
     if VerifySignatureAuth user pubkeyuser authmethod sigUser
27
      (assert (LogAuth user authmethod);
28
      relatechallenge user challenge;
29
       let resp = UserAuthRequest authmethod challenge sigUser in
30
      SendSaml user resp)
31
32
33
      SendSaml user (DisplayError 403)
    | LoginSuccess(status, issuer, destination) ->
34
     if (status = "OK") t
35
      let challenge = getuserchallenge user in
let authnReq = getauthnrequest user challenge in
36
37
      handleUserAuthenticated me user authnReq
39
40
      SendSaml user (DisplayError 403)
      _ -> SendSaml user (DisplayError 400)
```

Listing 4.13: The handling of the responses from Authentication Provider

This part of the identity provider handles the information received from the Authentication Provider. It has two match branches:

1. LoginResponseMessage which will prompt the user for a n factor authentication method while it relates the challenge generated by the Authentication Provider to the user for verification

2. LoginSuccess which specifies that the user has passed all the n factor authentication methods.

If the user has been successfully logged in the user will be issued an assertion which is done in the *handleUserAuthenticated* function. This function will also save a cookie that specifies that this user has logged in which the Identity Provider will search for when getting an *AuthnRequestMessage* from a user.

```
savejavascript: javascript:string -> unit
       savepublickey: owner:prin -> publickey:pubkey owner -> unit
   val connectwithauthp: me:prin -> authp:prin -> unit
   let connectwithauthp me authp =
      et req = NewSiteRequest me
       _ = SendMessage authp req in
    let resp = ReceiveMessage authp in
    match resp with
10
     ChallengeResponse(challenge) ->
11
     let _ = SendMessage authp (IdpChalResponse challenge) in
12
     let res = ReceiveMessage authp in
13
14
      atch res wi
       AcceptedIdp(idp, idppubkey, authp, authppubkey, signedjs)
      savejavascript signedjs;
17
      savepublickey authp authppubkey;
      savepublickey idp idppubkey
19
       _ -> res; ()
20
      _ -> resp; ()
```

Listing 4.14: Establising a secure connection with Authentication Provider

This part of the Identity Provider is the establishing of the secure connection between the Identity Provider and the Authentication Provider. Right now the challenge response from the Authentication Provider is just a nonce to illustrate that the Identity Provider needs to be investigated thoroughly by the Authentication Provider for the purpose of finding out if it is a non-evil Identity Provider.

4.5.8 Specification of the Database Handler

```
module Database

open Crypto
open CertStore
open TypeFunc

(*Identity provider functionality*)
val whitelist: idp:prin -> unit
val blacklist: idp:prin -> unit
val addidp: idp:prin -> bool
val whitelisted: idp:prin -> bool
```

```
createuser: user:prin -> userid:string -> password:string
       -> bool
      usercreation: user:prin -> generatedPassword:string -> bool
   val changeuserid: user:string -> newuser:string -> password:
       string -> bool
      changeuserpassword: user:string -> password:string ->

29
       bool
       revokedidp: user:string -> idp:prin -> bool
```

Listing 4.15: Specification of the database

The *Database* module is responsible for the communication with the database and therefore checking the information provided by the user. The database is also responsible for keeping track of how many n factor authentications the user has gone through. Note that as of now these functions are just specified by the *val* declaration and therefore has no concrete implementation.

4.5.9 Specification of the Authentication Provider

The specification of the Authentication Provider is divided into several listings for the sake of understandability.

```
module Authenticationprovider

open SamlProtocol
open Crypto
open Database
open TypeFunc
open Messaging

val relatechallenge: user:prin -> challenge:nonce -> unit

val verifychallenge: user:prin -> challenge:nonce -> bool

val nfactauth: me:prin -> idp:prin -> user:prin -> userid:
    string -> unit

let nfactauth me idp user userid =
    if (allnfactauthed userid) then
```

```
resetnfact userid;
17

74
      SendSaml idp (Failed Requester);
      authenticationprovider me idp user
76
      _ -> SendSaml idp (Failed Requester);
77
     authenticationprovider me idp user
```

Listing 4.16: Specification of the authentication provider

The Authentication Provider implements algorithms The Authentication Provider accepts two SAML messages LoginRequestMessage and NfactAuthRequest from the Identity Provider.

- 1. The LoginRequestMessage branch will check the login information. If the correct login information has been provided by the user it generates a nonce to be related to this user and specifies which type of n factor authentication the user has to go through and that will be sent to the Identity Provider.
- 2. The NfactAuthRequest branch is the receiving of n factor authentication response from the user. It verifies that the sender of the message is the correct user and the n factor information. The correct n factor information will make the function nfactauth which will handle if the user has gone through all n factor authentication method or needs to specify more. The function will the information to the Identity Provider.

```
val usercommunication: me:prin -> user:prin -> unit
   let rec usercommunication me user =
    let req = ReceiveMessage user in
    match req wi
     RequestForLogin(userid, password, email) ->
     if createuser user userid password email then

54
      usercommunication me user
55
56
57
      SendMessage user (StatusMessage Unsuccessful);
      usercommunication me user
58
        -> SendMessage user (StatusMessage Unsuccessful);
     usercommunication me user
```

Listing 4.17: The creation and changing of a user's account

This part of the Authentication Provider is responsible for creating and changing a user's account. It is pretty intuitive what the different messages does. When creating a login the user will give an email account where they will receive an email with a one-time password to verify their account. The database will handle all the information and the checking of the information.

```
val getsignedjavascript: string

val establishidp: me:prin -> idp:prin -> unit

let rec establishidp me idp =
 let req = ReceiveMessage idp in
 match req with
    | NewSiteRequest(idp) ->
    let challenge = GenerateNonce me in
```

```
relatechallenge idp challenge;
     SendMessage idp (ChallengeResponse challenge);
11
     establishidp me idp
12
     | IdpChalResponse(challenge) ->
13
     if (verifychallenge idp challenge) && (addidp idp) then
14
      let idppubkey = CertStore.GetPublicKey idp in
15
      let mypubk = CertStore.GetPublicKey me
let signedjs = getsignedjavascript in
16
17
       let resp = AcceptedIdp idp idppubkey me mypubk signedjs in
18
       SendMessage idp resp;
19
       establishidp me idp
20
21
       SendMessage idp (StatusMessage Unsuccessful);
22
       establishidp me idp
       _ -> SendMessage idp (StatusMessage Unsuccessful);
      establishidp me idp
```

Listing 4.18: Established a secure connection with the Identity Provider

This part of the Authentication Provider will handle the establishing of a secure connection between the Identity Provider and the Authentication Provider. As we mentioned when we described the Identity Provider's specification of this model there needs to be some investigation of the Identity Provider and not just a generated nonce. This is just specified to give an idea of how the model is designed.

4.5.10 Specification of the Browser

The specification of the Browser is divided into two listings for the sake of understandability. Note that we can not model the user's input therefore the input from the user is specified by a bunch of *val* declaration.

```
module Browser
   open SamlProtocol
   open Crypto
   open CertStore
   open TypeFunc
   open Messaging
   val loginWithFb: Authentication
   val loginWithGoogle: Authentication
   val loginWithSMS: Authentication
   val loginWithOpenId: Authentication
   val userid: string
   val password: string
   val email: string
16
   val fakeprint: str:string -> unit
17
   val handleAuthMethod: auth:Authentication -> Authentication
18
   let handleAuthMethod auth =
20
    match auth wi
21
      Facebook(fbid) -> loginWithFb
      Google(gid) -> loginWithGoogle
```

```
SMS(gen) -> loginWithSMS
25
       OpenId(oid) -> loginWithOpenId
26
    val loop: user:string -> idp:prin -> sp:prin -> unit
27
28
   let rec loop userid idp sp
29
     let loginresp = ReceiveSaml idp in
30
      match loginresp
31
32
        UserAuthRequest(authmethod, challenge, sigAuth) ->
       let authresponse = handleAuthMethod authmethod ir
33
       let authInfo = UserAuth userid authmethod authresponse in
let authresp = UserAuthResponse authInfo challenge sigAuth
34
35
       SendSaml idp authresp;
37
       loop userid idp sp
        AuthResponseMessage(idenp, dest, assertion) ->
38
39
       SendSaml sp loginresp
        _ -> loginresp; ()
40
   val browser: sp:prin -> res:uri -> unit
42
43
   let browser sp resource =
44
     let req = SPLogin resource
45
     let _ = SendSaml sp req in
      let res = ReceiveSaml sp in
47
48
        atch res w
      | AuthnRequestMessage(sp, idp, message, sigSP) ->
49
       let _ = SendSaml idp res in
50
       let idpResp = ReceiveSaml idp in
51
       match idpResp w
52
       | UserCredRequest(javascript, challenge, sigIdP) ->
let pubkissuer = CertStore.GetJSPublicKey idp in
53
54
55
        if VerifySignature idp pubkissuer javascript sigIdP then
         (assert (Log idp javascript);
let loginInfo = UserLogin userid password in
let loginreq = Login loginInfo challenge in
56
57
58
         SendSaml idp loginreq;
59
          loop userid idp sp;
         let spResp = ReceiveSaml sp in
61
62
          match spResp
          LoginResponse(str) ->
63
            fakeprint str
64
65
           _ -> spResp; ())
66
67
          fakeprint "Validation Error"
         _ -> idpResp; ()
        _ -> res; ()
```

Listing 4.19: Browser's side of logging in

This part of the *Browser* module is used to model the client's side of a logging in session. It is worth noticing that the *Browser* verifies the JavaScript is actually received from the correct Identity Provider. The function *fakeprint* is used to give the user messages about errors and if they are logged in. The recursive function *loop* will provide n factor authentication methods until the client receives a *AuthResponseMessage* which it then will send to the Service Provider

and the user is now logged in.

```
val newUserId: string
   val newPassword: string
   val idpToRevoke:string
   val nfactToRemove: Authentication
   val nfactToAdd: Authentication
   val retrieveGeneratedPassword: string
   val createUser: authp:prin -> unit

```

Listing 4.20: The Browser's side of the account creation and changing

This part of the *Browser* module is pretty straightforward. It specifies a lot of functions that will create the user's account and update the account by the user's wish. The nonce created when a user creates an account is used to relate the creation of account to a user.

4.6 Introducing adversaries

In the previous section we have been focused on implementation of the protocol according to the specification. This section will introduce adversaries into the protocol verification however we have not managed in this project to incorporate dedicated adversaries. Jacob introduced adversaries in his protocol verification through an abstract program and a main function to execute a protocol run. We have adopted this way of introducing an adversary and applied it to the OpenNemID protocol as shown in listing 4.21. The difference between our way of introducing an adversary and Jacob's is ours have the Authentication Provider also. The abstract attacker function is a parameter to the main function. This means that it is able to use any function defined in the modules. However it will not be able to call any assume command, i.e. every assertion in the Service Provider, Identity Provider and Authentication Provider will succeed.

```
module Main
   open SamlProtocol
   open Crypto
   open Serviceprovider
        Identityprovider
        Authenticationprovider
   val Fork: list (unit -> unit) -> unit
10
   let main attacker =
11
    Fork [ attacker;
12
     (fun () -> serviceprovider "serviceprovider.org" "browser"
         identityprovider.org");
     (fun () -> identityprovider
                                  "identityprovider.org" "browser"
14
         "authenticationprovider.org");
     (fun () -> authenticationprovider "authenticationprovider.org
           "identityprovider.org" "browser")]
```

Listing 4.21: Main module for introducing adversaries

It would be possible to model and mitigate known attacks on the protocol like Man In the Middle, authentication replay and session hijacking by modeling a

browser as part of the protocol model. We have modeled the browser but we have not modeled the aforementioned attacks due to time constraints.

4.7 State of the implementation

We have implemented the Identity, Service and Authentication Provider in the OpenNemID protocol and defined their abstract implementation but they are all missing session handling. Furthermore the implementations of the cryptographic elements and networking are abstract signatures only at the moment. If time had allowed it we could have incorporated the crypto and networking experiments done by Jacob into the model. As the previous section explained we have not modeled dedicated adversaries as a part of the present implementation either.
